

Generated benchmark artifacts

Typeset from `paper/generated/aarch64/` by `benchmarks/scripts/build_pdf.py`. Every number resolves to a row in the result set named below; see `PROVENANCE.md` for the inputs, transformation and caveats of each artifact.

Dataset	Metric	Matches per read			Potential		Buckets per read	
		possible	examined	in mapping	realized	unrealized	seeded	final

Table 2: Efficiency of the seed heuristic. Realized potential is possible matches divided by matches examined (work avoided); unrealized potential is matches examined divided by matches inside the reported mapping (work still wasted).

Figure 1: Whole-run speedup against thread count, Containment. The dashed line is linear speedup.

Figure 2: Peak resident memory against thread count, Containment, with the C++ reference as a horizontal line.

Figure 3: Per-read mapping time against the number of matches the read examined, Containment. Points are per-bin medians over reads grouped into 18 logarithmic bins; the shaded band is the interquartile range for the simulated set.

Figure 4: Where mapping time goes: stage shares of `query_mapping`, single-threaded.

Figure 5: The two headline results, per benchmark, single-threaded on both sides: wall-clock speedup over the C++ (top) and how many times less peak memory the port uses (bottom). The dashed line is parity.

Figure 6: Wall clock against thread count, Containment, with the C++ reference as a horizontal line. The gap at 1 is the single-threaded speedup the summary quotes; everything to the right of it is threading the C++ does not have.
